Correction to ‘The relative importance of rapid evolution for plant-microbe interactions depends on ecological context’

Casey P. terHorst, Jay T. Lennon and Jennifer A. Lau

Proc. R. Soc. B 281, 20140028 (22 June 2014; Published online 30 April 2014) (doi:10.1098/rspb.2014.0028)

In a recent publication [1], we reported the effects of contemporary drought and plant evolutionary responses to drought on several aspects of soil microbial communities, including fungal:bacterial ratios. The actual values reported in the paper are in fact bacterial:fungal ratios, rather than their reciprocal. Despite which ratio is used, the conclusions are qualitatively similar, although using the reciprocal ratio causes a change in sign of the effect sizes in figure 2; the magnitudes of the effects are identical. All references to F:B ratios in the paper should be read as B:F ratios.
